1. Basic of bifacial

1-1. What is bifacial?

Unlike conventional modules, the bifacial PV Module can produce energy from both the front and backside, utilizing sunlight on the front and reflected light on the back simultaneously.

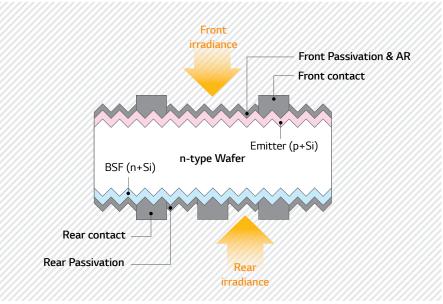

The bifacial PV module offer greater power output when compared to conventional monofacial PV modules, due to its ability to harvest light that is reflected onto the backside. The reflected light can come from a variety of sources, such as reflection from the ground or from a neighboring row of PV modules.

Bifacial Cell Design and Conventional Cell Design

- The bifacial cell is designed to absorb sunlight from both the front and the back.
- It has a symmetrical cell structure on the backside for additional sunlight absorption.

Front irradiance Front Passivation & AR Front contact Emitter (n+Si) P-type Wafer

Bifacial

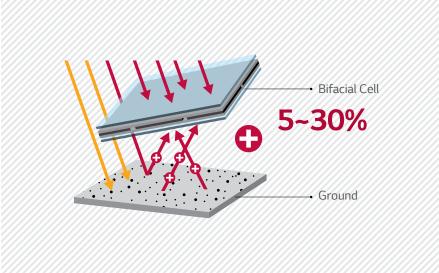

1. Basic of bifacial

1-1. What is bifacial?

Bifacial PV Module

- The bifacial PV Module doesn't use a white backsheet but uses a transparent backsheet (or glass) on the back.
- (Total produced energy) = (Energy from the front) + (Energy from the back)
- The bifacial PV Module's performance depends on various conditions, such as system design, installation methods, location, etc.

Benefits

- Competitive LCOE can be achieved
- Increased Energy
- Cost saving effect depends on the amount of bifacial gain

1. Basic of bifacial

2-1. Albedo

Albedo

Albedo is represented as the ratio of light reflected from various sources of surface compared to incident radiation. The albedo has a range across a variety of surfaces, where 0% equates to no reflected light, and 100% represents perfect reflection. The more reflected light (i.e., higher albedo) shining on to the backside of a bifacial module, the more power generated.

$$Albedo = \frac{Reflected Light}{Incident Light}$$

Albedo is the most critical factor that affects the energy production from the backside of the bifacial module.

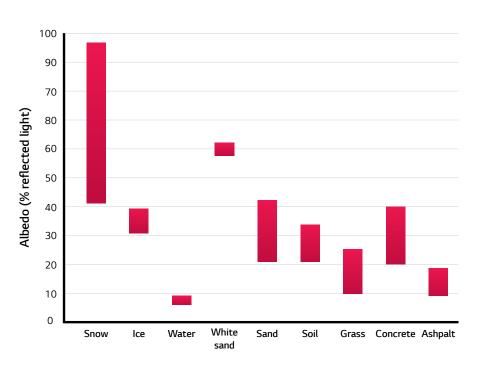

Albedo and reflectance have different definitions. Albedo refers to the overall solar radiation reflectance (full spectrum of light) whereas reflectance refers to the visible light spectrum only.

However, Albedo is also referred as Solar Reflectance.

Albedo has a various range of values because it is dependent on environmental conditions. (i.e. weather conditions, time change, surface conditions)

It is not easy to predict the exact albedo value of a specific area.

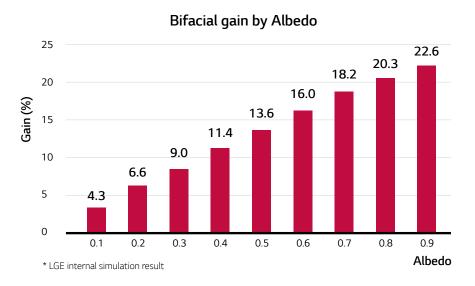

Albedo range for a variety of surface

2-1. Albedo

How to determine the Albedo

The first step towards project design is to identify the albedo. This is very important because the albedo directly impacts the bifacial gain. There are 3 main methods for determining the albedo value:

1. Using Albedo reference table

- Site inspection (Ground color, material, ground condition, etc.)
- Look for expected albedo from table (i.e. PVsyst)

2. Measure the albedo of the site with a pyranometer (recommended)

- Install the albedometer on the center of the site (ISO-9060 first class rated device is recommended)
- Install the albedometer at least 0.5m from the ground
- Collect data with the equipment
- Avoid obstacles and shading around the albedometer
- Measure albedo over 5 different spots around the site for greater accuracy

3. Measurement with PV module

- Install the PV module on a mounting structure (installation site)
- Note that the PV module will measured while being installed in different locations of the array for better albedo accuracy
- Measure the module in each location: one measurement(Isc) while facing the sky and another measurement(Isc) while facing the ground
- Measure the lsc of the module over 5 different locations on the installation site using the same procedure
- Find the albedo using the equation shown on the right
- Determine the mean value of albedo from every measured location

Surface	Albedo
Grass	0.15 - 0.25
Fresh snow	0.82
Wet snow	0.55-0.75
Dry asphalt	0.09-0.15
Concrete	0.25-0.35
Aluminum	0.85
New galvanized steel	0.35
Very dirty galvanized	0.08

^{*} Source : PVsvst

Albedometer

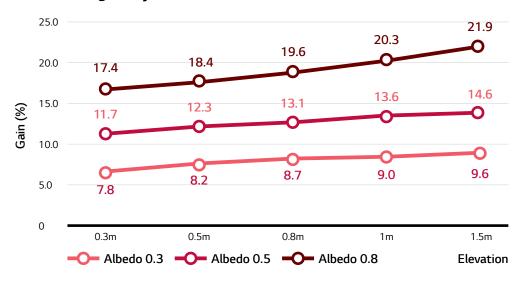

2-2. Module Elevation

Module Elevation

Ilt is important to secure enough space between the module and the ground for more sunlight reflectance, resulting in a greater bifacial gain. Thus, the height of the module is also one of the main factors that has a significant impact on bifacial gain.

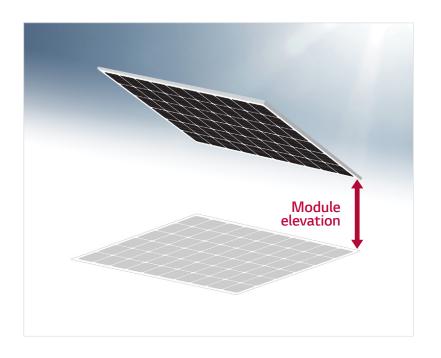

The module height (elevation) is defined as the distance between the bottom of the lowest part of the module and the ground (surface). Based on internal simulation, bifacial gain value kept increasing with module height moving up to 1m. However, if the module height went over 1m (39.37 in), the bifacial gain would be saturated.

Bifacial gain by module elevation

^{* 1}MW system

^{*} Fixed tilt structure

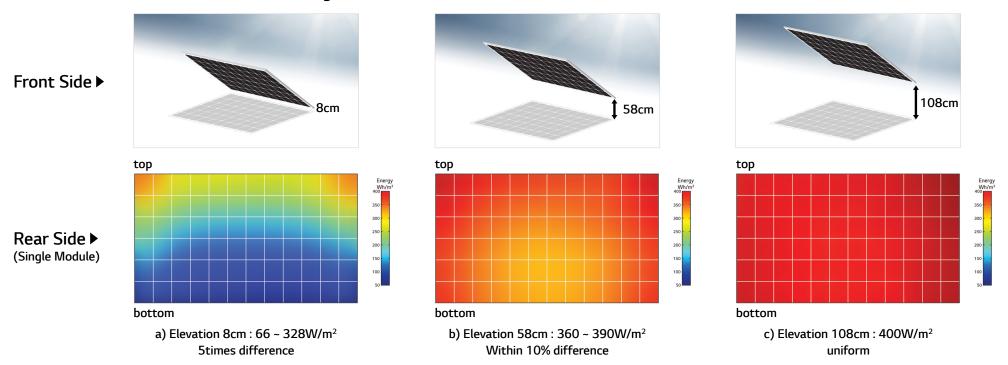

^{* 2} rows Landscape

2-2. Module Elevation

Irradiance uniformity on the backside of the module

Not only does it affect the irradiance on the backside, the module height also affects the reflected light uniformity. If the module height is low, the amount of irradiance on the backside is different on certain parts of the module due to its own shadow. The cells near the top edge of module absorbs more light than the cells on the rest of the module. When the module elevation is at 5cm, the range of irradiance exposed to the backside of the module is rather larger, the highest measurement is 5 times higher than the lowest value recorded. As module elevation increases, the irradiance values are more uniform throughout the module. This is important because irradiance uniformity results in mismatch loss from the module and array, which ultimately leads to energy loss.

Irradiance Distribution of Backside in Single Module

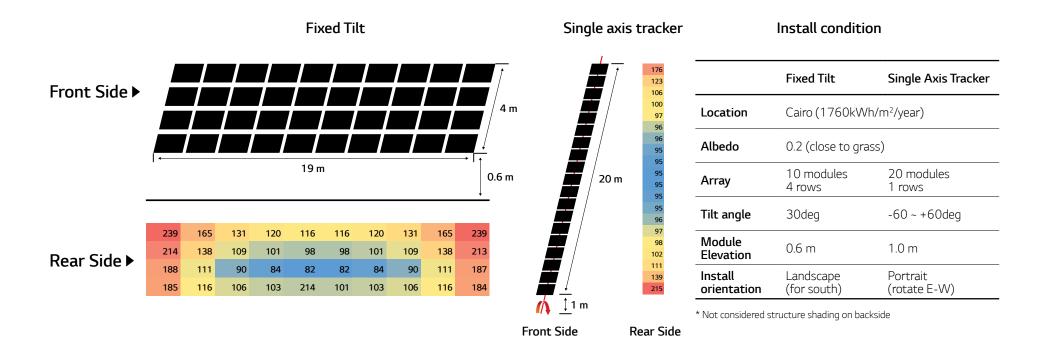

^{*} Source : PV MODULE POWER GAIN DUE TO BIFACIAL DESIGN. PRELIMINARY EXPERIMENTAL AND SIMULATION DATA. (2010 IEEE)

^{*} Test condition: horizontal irradiation 1006W/m2, Albedo 50%, Tilt angle 30deg

2-2. Module Elevation

Irradiance uniformity on the array

There is also an irradiance uniformity difference by module location in an array regardless of the array being fixed tilt or single axis tracker. The bifacial gain of the array or system is determined by the module performance with the lowest irradiation. It is very helpful to understand irradiance distribution on backside of array to plan cable routes in series and reduce mismatch loss.

^{*} Source: MODELLING OF SINGLE-AXIS TRACKING GAIN FOR BIFACIAL PV SYSTEMS (32nd European Photovoltaic Solar Energy Conference and Exhibition)

2-3. Pitch

Pitch (GCR)

Pitch is the distance from front array to behind. Pitch is directly correlated with the Ground Coverage Ratio (GCR). The Ground Coverage Ratio (GCR) is the ratio of the PV modules area and the total ground area.

$$GCR = \frac{\text{module area}}{\text{ground area}}$$

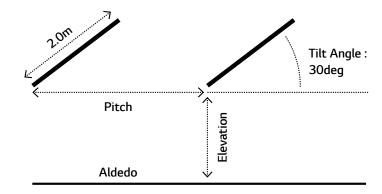

As the value of GCR increases, both the Pitch value as well as the installation area decreases.

i.e. Typical GCR value with low shading loss (<2%)

Fixed tilt: 0.55

Single axis tracker: 0.35 Dual axis tracker: 0.20

Pitch (or GCR) is another important factor that affects the bifacial gain. A high Pitch value (low GCR) provides a greater possibility of more energy production. As a result, the Pitch should be considered while designing the system.

Bifacial gain by GCR

2-4. Shading

Mounting structure

The mounting structure, especially the mounting rail, blocks reflected sunlight that comes to the backside of module. The shading produced by the mounting structure decrease bifacial gain. The loss of the backside gain depends on various factors associated with the module and the mounting structure, shown below:

- 1) Rail thickness and width
- 2) Number of rails below module
- 3) Rail design
- 4) Distance

The best way to minimize loss is to use and install a mounting structure optimized for the bifacial PV Module (i.e. rail edge on module frame)

Other ways to maximize bifacial gain from the backside are

- 1) To make smaller array configurations
- 2) To minimize number of rows in array

The optimized design for bifacial PV module gives more energy production because of better irradiance uniformity.

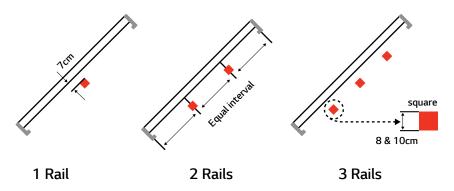

Mounting structure for bifacial (Rail on edge of module)

2-5. Array Design

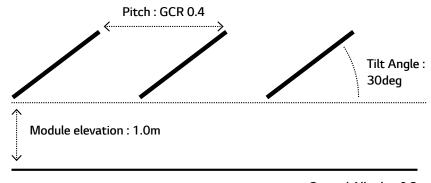

Array Design

The bifacial gain is affected by the number of rows in the array. Based on the ground mount (fixed tilt system), the bifacial gain increases as the number of rows decrease, from 4 rows to 1 row. Therefore, you will be able to see an increase in overall performance by minimizing the number of rows in your overall system.

3-1. Electrical Design for Bifacial PV System

Electrical Behavior of Bifacial PV Module

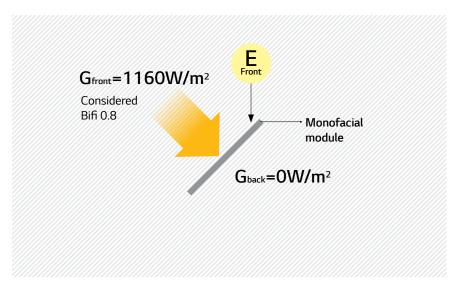

The Bifacial PV Module produces more energy by absorbing the light on the frontside and the backside simultaneously. As a result, the total produced energy of the Bifacial PV Module is calculated by the sum of energy from the frontside and the backside of the module. The bifacial output power can be viewed as a monofacial module producing energy from the total sum of sunlight exposed to the frontside and the backside of the bifacial module.

When there is a certain amount of bifacial gain, the electrical behavior of bifacial PV module is almost equivalent as that of a monofacial with higher output power, which from the sum of the irradiance exposed to the front and the backside of the bifacial module.

Bifacial module

G_{front}=1000W/m² Bifacial module G_{back}=200W/m²

Monofacial module

$$E_{Front}$$
 + E_{Back} = E_{Front} (under sum of irradiance)

3-1. Electrical Design for the Bifacial PV system

Electrical Specifications of the bifacial PV module

It is very important to identify the estimated bifacial gain before designing the system. After determining the expected bifacial gain under the conditions mentioned before, the electrical components (inverters, cables, protection devices, etc.) used in the bifacial system must be calculated and selected based on electrical properties of bifacial PV module according to the additional bifacial gain. For example, if the system is expected to produce 10% gain, the electrical properties shown for 10% bifacial gain (highlighted in red below) should be used.

Na del		LC200N2T AF	Bifacial gain**				
Model		LG390N2T-A5 –	5%	10%	20%	30%	
Maximum Power (Pmax)	[W]	390	410	429	468	507	
MPP Voltage (Vmpp)	[V]	41.4	41.4	41.4	41.5	41.5	
MPP Current (Impp)	[A]	9.43	9.90	10.36	11.28	12.22	
Open Circuit Voltage (Voc)	[V]	49.2	49.2	49.2	49.3	49.3	
Short Circuit Current (Isc)	[A]	10.15	10.15	11.17	12.18	13.20	

3-2. Inverter sizing

Inverter sizing

Two factors should be considered when choosing an inverter for the bifacial PV System.

1. Max Input Current of the Inverter

The current (Isc) value of the Bifacial PV Module is increased by backside boost, where the voltage of the bifacial is constant. As a result, the current increases around 20% when the bifacial gain is at 20%. Check the max input current rating of the inverter and see if the inverter is rated to satisfy the increased current from the bifacial module.

2. Inverter Sizing

If there is no compulsory regulation for inverter sizing, use the inverter sizing methodology of a conventional monofacial module. However, use the real power (gained power) rather than the nominal power of the bifacial PV module. For example, if a 10% gain is expected, then refer to the power associated with the 10% gain instead of the nameplate rating of the module.

It is important to consider the DC-AC ratio and the clipping loss rate when selecting the inverter size. The DC-AC ratio and the clipping loss will be increased by the power gain. If you would like to maintain the same clipping loss value related to a monofacial module with the same nameplate rating, you should use the total power from the bifacial module and either scale down the DC capacity of the system or scale up the AC inverter capacity. However, if the clipping loss only increases slightly (increases under 1-2%), it may be more efficient to use same capacity of inverter without sizing up.

3-2. Inverter sizing

Inverter sizing (Example)

The system configuration below is for a site using a 390W bifacial module with a bifacial gain of about 10%. The bifacial PV system has more clipping loss due to the higher DC-AC ratio caused by the increased module output power.

		Bifacial (10% gain assumed)				
	Monofacial	1. same configuration (DC-AC ratio up)	2. same clipping loss (reduce module qty)	3. same clipping loss (increase AC capacity)		
DC capacity	100kW	107.25kW	99.95kW	107.25kW		
- Module nominal power	400W	390W	390W	390W		
- Module real power	-	429W	429W	429W		
- Module quantity	250	250	233	250		
AC capacity (Inverter)	83kW	83kW	83kW	Above 97.5kW		
DC-AC ratio	120.4%	128.9%	120.6%	120.6%		
Clipping loss	0.6%	2.7%	0.6%	0.6%		

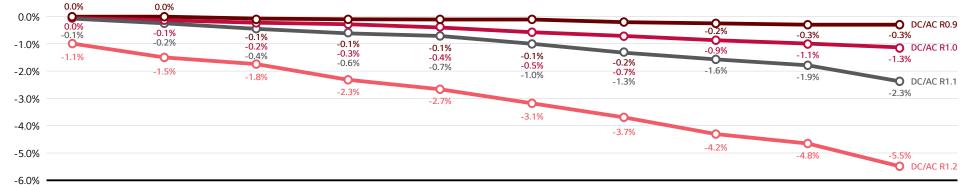

- 1. If the increased clipping loss of the bifacial system is in an acceptable range, use Method No.1.
- 2. If clipping loss is required to be equivalent as that when using a monofacial system with the same nameplate rating (390W), then either:
 - Decrease DC capacity by reducing the module quantity (Method No. 2)
 - Increase AC capacity by sizing up the inverter (Method No. 3)

3-2. Inverter sizing

Guideline for inverter sizing considering clipping loss

0.9 —	Bifacial gain	26.0%	24.8%	23.6%	20.8%

3-3. Consideration for using MLPE

Guideline for using MLPE devices

When using power optimizers on Bifacial PV modules, use the specifications of associated with the nominal power of the module (highlighted by the red box below). Power optimizer manufacturers suggest that the electrical properties of the module shall not exceed the input spec of the power optimizer. *Following user guideline by the power optimizer manufacturer is highly recommended.

Check the electrical values associated to the nominal power.

(1) Check Isc, Voc and Pmax value of bifacial module.

ex) LG390N2T

Isc - 10.15

Voc-49.2V

Pmax-390W

- (2) Find compatible MLPE devices that satisfy module input specs.
 - Maximum input current and voltage of devices should be higher than lsc and Voc of the module.

(Applying safety factor 1.25 is recommended)

Electrical Properties(STC*)

Model		LG390N2T-A5	Bifacial Gain			
		LG390NZ1-A5	10%	20%	30%

Module Efficiency	[%]	18.5	20.3	22.1	24.0	

Front at STC

- (3) Using an optimizer that has a lower input power than the nominal power of the bifacial module is not allowed according to manufacturer guide.
 - For example, the power optimizer rated for 380W should not be operated with 390W bifacial even if the current and voltage ratings are compatible.
 - In contrast, a microinverter is allowed to be used regardless of the Pmax of the bifacial. (clipping loss will occur depending on the operating conditions of the bifacial module.)

* GCR 0.5

* Portrait: 2stacks

Expected BiFacial Energy Yield Gain with Ground Mount (Portrait 2 stacks)

Albedo [%]	Surface in practical					
Albedo [70]	Surface in practical	0.3	0.5	0.8	1	1.5
15	Soil, meadows	4.0%	4.0%	4.5%	4.6%	5.0%
30	Dirt, Grave, Concrete	7.0%	7.4%	7.9%	8.3%	9.0%
50	Sand	10.9%	11.6%	12.5%	13.0%	14.2%
70	Snow	14.8%	15.7%	16.8%	17.6%	19.2%
85	White membrane	17.6%	18.7%	20.1%	21.0%	22.8%

^{*} Note 1 : Based on PVsyst 6.72

Albedo [%]	Surface in practical	Axis height from ground [m]					
Albedo [70]	Surface in practical	1	1.5	2	2.5	3	
15	Soil, meadows	3.8%	4.2%	4.5%	4.5%	4.5%	
30	Dirt, Grave, Concrete	6.6%	7.5%	7.9%	8.0%	8.0%	
50	Sand	10.2%	11.8%	12.5%	12.6%	12.6%	
70	Snow	13.8%	15.8%	16.6%	16.8%	16.8%	
85	White membrane	16.3%	18.6%	19.5%	19.7%	19.7%	

^{*} Note 1 : Based on PVsyst 6.72

^{*} Note 2: Shading by mounting structure in not considered.

4-2. LG BiFacial gain simulation

Additional yield simulation (Toronto, Canada)

* Site and installation condition

- * Location : Latitude 43.67 / longitude : -79.4
- * Global Horizontal irradiation(GHI): 1,296[kwh/m²)

Expected BiFacial Energy Yield Gain with Ground Mount (Portrait 2 stacks)

Albedo [%]	Surface in practical		Module height from ground [m]					
Albedo [70]	Surface in practical	0.3	0.5	8.0	1	1.5		
15	Soil, meadows	4.8%	5.0%	5.3%	5.4%	5.7%		
30	Dirt, Grave, Concrete	7.7%	8.1%	8.7%	9.0%	9.6%
